

# Optimized Visibility Motion Planning for Target Tracking and Localization

Hongchuan Wei<sup>†</sup>, Wenjie Lu<sup>†</sup>, Pingping Zhu<sup>†</sup>, Guoquan Huang<sup>‡</sup>, John Leonard<sup>‡</sup>, and Silvia Ferrari<sup>†</sup>

**Abstract**—This paper presents a visibility-based method for planning the motion of a mobile robotic sensor with bounded field-of-view such that its ability to simultaneously track a moving target and localize its position is optimized. The target state is estimated from online sensor measurements and a set of known landmarks, using an extended Kalman filter (EKF), and thus the method is applicable to robots without a global positioning system. It is shown that the problem of optimizing the target tracking and robot localization performance is equivalent to optimizing the visibility or probability of detection in the EKF framework under mild assumptions. The control law that maximizes the probability of detection for a robotic sensor with a sector-shaped field-of-view is derived as a function of the robot heading and aperture. Simulations have been conducted on synthetic experiments and the results show that the optimized-visibility approach is effective at minimizing target loss, and outperforms an existing potential method based on robot trailer models.

## I. INTRODUCTION

The problem of tracking moving targets using mobile robotic sensors arises in a number of monitoring and surveillance applications [1]–[4]. In many cases, the ability to track and localize the target is limited by the absence of a global positioning system (GPS), for example due to GPS-denied environments, and by a bounded field-of-view (FoV) or visibility region, which may cause the sensor to lose the target completely. These difficulties are exacerbated by the need for tracking moving targets in complex unstructured environments, in which target loss may cause unbounded tracking errors if the lost target can not be retrieved. Furthermore, since the position and orientation of the sensor FoV is determined by the control inputs, the motion of the robotic sensor must be planned in concert with its measurement sequence for both sensing and navigation objectives to be optimized [5], [6].

An optimized robot motion planning algorithm has been recently proposed in [7] for leader-follower formation problems in which the follower seeks to minimize the uncertainty in its relative position and heading with respect to the leader. A gradient-based active target-tracking method for robots equipped with 3D range finder sensors was proposed in [8] for minimizing the uncertainty in robot and target position estimates. These methods, however, do not account for bounded FoVs, but assume the target is always within range of the sensor. Cell decomposition [9], [10], probabilistic

roadmap methods [11], [12], and potential field methods [13] have been proposed for planning the motion of a robotic sensor with a bounded FoV in order to optimize its ability to classify *stationary* targets, in an obstacle-populated environment. Geometric transversal methods have been developed for planning the motion of omnidirectional sensors such that their probability of detecting a moving target is optimized [14]–[16]. Other visibility-based methods that account for both the sensor kinodynamic constraints and bounded FoV have been proposed in [17]–[20]. However, all of these methods assume that the sensor state with respect to an inertial frame of reference is known at all times without error.

This paper presents a optimized-visibility method that is applicable to robots equipped with exteroceptive sensors, such as laser scanners or cameras, for tracking and localizing moving targets, and with proprioceptive sensors, such as odometers, for estimating their position and orientation without the aid of a GPS. It is assumed that both the robot and the target state can be estimated from onboard measurements using an extended Kalman filter (EKF) [21], [22]. It is also assumed that the FoV of the exteroceptive sensor can be approximated by a sector with a fixed orientation with respect to the robot, and a fixed aperture or central angle. The robot is assumed to obey unicycle kinematics, and the target motion is assumed governed by a stochastic motion model with Gaussian noise. The measurement noise is also assumed Gaussian for both exteroceptive and proprioceptive sensors, and the exteroceptive measurement models for the moving target and the landmarks are nonlinear. Under these assumptions, a control law that maximizes the target probability of detection is obtained in analytic form. The results show that the proposed method is effective at tracking and localizing a moving target with low target loss rates, and outperforms an existing potential method based on robot trailer models [23].

## II. PROBLEM FORMULATION

Consider a mobile robotic sensor, hereon referred to as robot, deployed to track a moving target in a 2D workspace,  $\mathcal{W} \subset \mathbb{R}^2$ , that is convex [24]. The robot kinematics in  $\mathcal{W}$  can be described by the unicycle motion model [25],

$$\dot{\mathbf{q}}_r = \begin{bmatrix} \cos \theta_r & 0 \\ \sin \theta_r & 0 \\ 0 & 1 \end{bmatrix} \mathbf{u}_r \quad (1)$$

where  $\mathbf{q}_r = [x_r \ y_r \ \theta_r]^T$  is the robot configuration or *state* with respect to an inertial (or global) frame of reference  $\mathcal{F}_{\mathcal{W}}$ ,  $\mathbf{u}_r = [v_r \ \omega_r]^T$  is the robot control vector,  $v_r$  denotes the

translational speed,  $\omega_r$  is the angular velocity, and  $\mathbf{u}_r \in \mathcal{U}$ , where  $\mathcal{U} = [v_{\min}, v_{\max}] \times [\omega_{\min}, \omega_{\max}]$  is the space of admissible control inputs.

Assume the robot velocity and heading remain constant during every time interval  $\delta t$ , and let  $k$  denote the discrete time index. Then, the agent state propagation equations can be obtained as follows [26],

$$\mathbf{q}_r(k+1) = \mathbf{q}_r(k) + \mathbf{B}_r(k)\mathbf{u}_r(k) \triangleq \mathbf{f}_r[\mathbf{q}_r(k), \mathbf{u}_r(k), k], \quad (2)$$

where

$$\mathbf{B}_r(k) = \begin{bmatrix} \cos \theta_r(k)\delta t & 0 \\ \sin \theta_r(k)\delta t & 0 \\ 0 & \delta t \end{bmatrix}. \quad (3)$$

The proprioceptive sensor (e.g. odometer) obtains noisy measurements of the control vector,

$$\mathbf{z}_r(k) \triangleq \mathbf{h}_r[\mathbf{u}_r(k)] = \mathbf{u}_r(k) + \mathbf{v}_r(k), \quad (4)$$

where  $\mathbf{v}_r(k)$  is white Gaussian noise with a time-invariant and known covariance matrix  $\mathbf{Q}_r$ , i.e.,  $\mathbf{v}_r(k) \sim \mathcal{N}(\mathbf{0}, \mathbf{Q}_r)$ .

The robot is also equipped with an exteroceptive sensor characterized by a sector-shaped FoV, denoted by  $\mathcal{S} \subset \mathcal{W}$ , that is rigidly connected to the robot, and has an aperture or central angle  $\alpha$ , and a range or radius  $\gamma$ , as shown in Fig. 1. Then, the motion of any point in  $\mathcal{S}$  can be described by the robot configuration vector  $\mathbf{q}_r$ , which includes the robot inertial position  $\mathbf{x}_r = [x_r \ y_r]^T$ , and heading  $\theta_r$ . Let the target state be denoted by  $\mathbf{q}_t = [x_t \ y_t \ \dot{x}_t \ \dot{y}_t]^T$ , where  $\mathbf{x}_t = [x_t \ y_t]^T$  is the target position, and  $\dot{\mathbf{x}}_t = [\dot{x}_t \ \dot{y}_t]^T$  is the target velocity. When the target is inside the FoV, the exteroceptive sensor can measure its relative distance and bearing according to the model [27],

$$\mathbf{z}_t \triangleq \mathbf{h}_t(\mathbf{q}_r, \mathbf{q}_t) = \begin{cases} [\rho_t^2 & \theta_t]^T + \mathbf{v}_t, & \mathbf{x}_t \in \mathcal{S}(\mathbf{q}_r) \\ \emptyset, & \mathbf{x}_t \notin \mathcal{S}(\mathbf{q}_r) \end{cases} \quad (5)$$

where  $\rho_t = \|\mathbf{x}_r - \mathbf{x}_t\|$  denotes the Euclidean distance between  $\mathbf{x}_r$  and  $\mathbf{x}_t$ ,  $\theta_t$  is the angle between the robot heading and the direction from robot to target.  $\mathbf{v}_t$  is zero-mean Gaussian noise with covariance  $\mathbf{R}_t$ . The workspace  $\mathcal{W}$  is populated with  $L$  stationary landmarks with positions  $\mathbf{x}_l = [x_1 \ y_1 \ \dots \ x_L \ y_L]^T$  that can be used to aid localization. The measurement of the landmarks also consists of the relative distance and bearing,

$$\mathbf{z}_{l_i} \triangleq \mathbf{h}_l(\mathbf{q}_r, \mathbf{x}_{l_i}) = \begin{cases} [\rho_{l_i}^2 & \theta_{l_i}]^T + \mathbf{v}_{l_i}, & \mathbf{x}_{l_i} \in \mathcal{S}(\mathbf{q}_r) \\ \emptyset, & \mathbf{x}_{l_i} \notin \mathcal{S}(\mathbf{q}_r) \end{cases} \quad (6)$$

for  $i = 1, \dots, L$ , where  $\rho_{l_i} = \|\mathbf{x}_r - \mathbf{x}_{l_i}\|$  and  $\theta_{l_i}$  is the relative angle between the robot heading and the  $i$ th landmark location.  $\mathbf{v}_{l_i}$  is zero-mean Gaussian noise with covariance  $\mathbf{R}_{l_i}$ .

The target motion in  $\mathcal{W}$  is assumed governed by a linear stochastic motion model that, in discrete time, can be written as a difference equation,

$$\mathbf{q}_t(k+1) = \Phi_t \mathbf{q}_t(k) + \mathbf{G} \mathbf{w}(k) \triangleq \mathbf{f}_t[\mathbf{q}_t(k)] + \mathbf{G} \mathbf{w}, \quad (7)$$

where  $\mathbf{w}$  is zero-mean white Gaussian noise with covariance

Fig. 1. FoV of exteroceptive sensor.

matrix  $\mathbf{Q}_t$ ,  $\Phi_t$  is the state transition matrix, and  $\mathbf{G}$  is the noise Jacobian matrix, both of which are assumed to be time invariant and known *a priori*.

Based on the above robot and target motion model, and the latest proprioceptive and exteroceptive measurements,  $\mathbf{z}_r(k)$ ,  $\mathbf{z}_t(k)$  and  $\mathbf{z}_l(k)$ , the goal is to obtain a control law for the unicycle robot (1) such that its ability to track and localize the target (7) is optimized without losing the target. The sensor tracking and localization accuracy, presented in Section IV-A, are obtained from the EKF presented in the next section.

### III. EKF ROBOT LOCALIZATION AND TARGET TRACKING

In the absence of GPS or other information on the robot position in inertial frame, an EKF method can be used to estimate both the robot and the target state from the proprioceptive and exteroceptive measurements described in the previous section. Consider an augmented state vector containing both the robot and the target state,

$$\mathbf{q}(k) = [\mathbf{q}_r^T(k) \ \mathbf{q}_t^T(k)]^T, \quad (8)$$

and the augmented control vector

$$\mathbf{u}(k) = [\mathbf{u}_r^T(k) \ \mathbf{0}^T]^T. \quad (9)$$

Based on the robot state propagation equation (2) and the target state propagation equation (7), the joint state propagation of the robot and the target is

$$\mathbf{q}(k+1) = \mathbf{f}[\mathbf{q}(k), \mathbf{u}(k), k] = \begin{bmatrix} \mathbf{f}_r[\mathbf{q}_r(k), \mathbf{u}_r(k), k] \\ \mathbf{f}_t[\mathbf{q}_t(k)] \end{bmatrix} \quad (10)$$

and the Jacobian matrix of the state transition function for the joint state is

$$\Phi = \begin{bmatrix} \Phi_r(k) & \mathbf{0} \\ \mathbf{0} & \Phi_t \end{bmatrix}, \quad (11)$$

Fig. 2. Illustration of the changes of the robot FoV due to the translation and rotation of the robot.

where

$$\begin{aligned} \Phi_r(k) &\triangleq \frac{\partial}{\partial \mathbf{q}_r(k)} \{ \mathbf{f}_r[\mathbf{q}_r(k), \mathbf{u}_r(k), k] \} \\ &= \begin{bmatrix} 1 & 0 & -\sin \theta_r(k) v_r(k) \delta t \\ 0 & 1 & \cos \theta_r(k) v_r(k) \delta t \\ 0 & 0 & 1 \end{bmatrix}. \end{aligned} \quad (12)$$

In the EKF, the prediction of the joint state and its covariance before the measurements is given by,

$$\hat{\mathbf{q}}(k+1|k) = \mathbf{f}[\hat{\mathbf{q}}(k|k), \mathbf{u}(k), k] \quad (13)$$

$$\mathbf{P}(k+1|k) = \Phi \mathbf{P}(k|k) \Phi^T + \begin{bmatrix} \mathbf{B}_r(k) \mathbf{Q}_r \mathbf{B}_r^T(k) & \mathbf{0} \\ \mathbf{0} & \mathbf{G} \mathbf{Q}_t \mathbf{G}^T \end{bmatrix} \quad (14)$$

The Jacobian matrix of the measurement function  $\mathbf{h} \triangleq [\mathbf{h}_t^T \quad \mathbf{h}_l^T]^T$  is [29]

$$\mathbf{H}(k) = \begin{bmatrix} \frac{2(x_r - x_t)}{\|\mathbf{x}_r - \mathbf{x}_t\|} & \frac{2(y_r - y_t)}{\|\mathbf{x}_r - \mathbf{x}_t\|} & 0 & \frac{2(x_t - x_r)}{\|\mathbf{x}_r - \mathbf{x}_t\|} & \frac{2(y_t - y_r)}{\|\mathbf{x}_r - \mathbf{x}_t\|} & 0 \\ 0 & 0 & 1 & 0 & 0 & 1 \\ \frac{2(x_r - x_1)}{\|\mathbf{x}_r - \mathbf{x}_{l_1}\|} & \frac{2(y_r - y_1)}{\|\mathbf{x}_r - \mathbf{x}_{l_1}\|} & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ \frac{2(x_r - x_L)}{\|\mathbf{x}_r - \mathbf{x}_{l_L}\|} & \frac{2(y_r - y_L)}{\|\mathbf{x}_r - \mathbf{x}_{l_L}\|} & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \end{bmatrix} \quad (15)$$

Then the EKF posterior estimates are computed as follows :

$$\tilde{\mathbf{y}}(k+1) = \begin{bmatrix} \mathbf{z}_r^T(k+1) \\ \mathbf{z}_l^T(k+1) \end{bmatrix} - \mathbf{h}[\hat{\mathbf{q}}(k+1|k)] \quad (16)$$

$$\begin{aligned} \mathbf{S}(k+1) &= \mathbf{H}(k+1) \mathbf{P}(k+1|k) \mathbf{H}(k+1)^T \\ &\quad + \begin{bmatrix} \mathbf{R}_r & \mathbf{0} \\ \mathbf{0} & \text{diag}([\mathbf{R}_t \quad \dots \quad \mathbf{R}_t]) \end{bmatrix} \end{aligned} \quad (17)$$

$$\mathbf{K}(k+1) = \mathbf{P}(k+1|k) \mathbf{H}(k+1)^T \mathbf{S}^{-1}(k+1) \quad (18)$$

$$\hat{\mathbf{q}}(k+1|k+1) = \hat{\mathbf{q}}(k+1|k) + \mathbf{K}(k+1) \tilde{\mathbf{y}}(k+1) \quad (19)$$

$$\mathbf{P}(k+1|k+1) = [\mathbf{I} - \mathbf{K}(k+1) \mathbf{H}(k+1)] \mathbf{P}(k+1|k) \quad (20)$$

where  $\text{diag}(\cdot)$  denotes the square diagonal matrix with the blocks of matrices on the main diagonal.

#### IV. VISIBILITY-BASED ROBOT MOTION PLANNING

This section presents a motion planning method for optimizing the tracking and localization performance of the exteroceptive robotic sensor described in Section II, based on the output of the EKF algorithm presented in Section III. In what follows, an objective function, representing the sensor performance, is first presented. Then, a control law that optimizes the sensor performance by guiding the robot to obtain the best next measurements is derived.

##### A. Tracking and Localization Performance

In GPS-denied environments, the quality of target state estimates depends on the estimates of the robot state, as obtained by the EKF algorithm and the proprioceptive sensor measurements. Therefore, the overall target tracking and localization performance can be represented by the expected power of the error between the true and estimated robot and target states,

$$\begin{aligned} J[\mathbf{u}_r(k)] &= (1 - P_d) \mathbb{E} [\mathbf{e}(k+1|k)^T \mathbf{e}(k+1|k)] \\ &\quad + P_d \mathbb{E} [\mathbf{e}(k+1|k+1)^T \mathbf{e}(k+1|k+1)] \end{aligned} \quad (21)$$

where,

$$\mathbf{e}(k+1|k) = \mathbf{q}(k) - \hat{\mathbf{q}}(k+1|k), \quad (22)$$

$$\mathbf{e}(k+1|k+1) = \mathbf{q}(k) - \hat{\mathbf{q}}(k+1|k+1), \quad (23)$$

and  $\mathbb{E}(\cdot)$  denotes the expectation.  $P_d$  is the probability that the target measurement is available, and is a function of the robot state. To define  $P_d$ , we integrate the target state distribution over the robot's FoV,

$$P_d[\mathbf{q}_r(k)] = \int_{\mathbf{x}_t(k)} f_t[\mathbf{x}_t(k)] \mathbb{1}_{S[\mathbf{q}_r(k)]}[\mathbf{x}_t(k)] d\mathbf{x}_t(k) \quad (24)$$

where  $\mathbb{1}_A(x)$  is the indicator function: it is one if  $x \in A$  and zero otherwise.  $f_t[\mathbf{x}_t(k)]$  is the probability density function

(PDF) of target state distribution, which can be approximated by Gaussian distributions, as follows,

$$f_t[\mathbf{x}_t(k)] = \mathcal{N}[\mathbf{x}_t(k); \hat{\mathbf{x}}_t(k|k-1), \mathbf{P}_t(k|k-1)] \triangleq \mathcal{N}[\mathbf{x}_t(k); \boldsymbol{\mu}_t(k), \boldsymbol{\Sigma}_t(k)], \quad (25)$$

where,  $\boldsymbol{\mu}_t(k)$  and  $\boldsymbol{\Sigma}_t(k)$  are introduced only to simplify our ensuing derivations. Then (21) can be rewritten as

$$J[\mathbf{u}_r(k)] = \text{tr}[\mathbf{P}(k+1|k)] - P_d \times \{\text{tr}[\mathbf{P}(k+1|k)] - \text{tr}[\mathbf{P}(k+1|k+1)]\} \quad (26)$$

where  $\text{tr}(\cdot)$  denotes the trace of a matrix. Since the propagation step of EKF produces prior estimate of the joint state only, in this paper we focus on controlling robot to get the most informative measurements to reduce the uncertainty of the joint state. Therefore, it is assumed that the prior estimates are optimal with respect to the robot control. In addition, for the priori and posteriori state estimates in the EKF, it is true that

$$\text{tr}[\mathbf{P}(k+1|k)] - \text{tr}[\mathbf{P}(k+1|k+1)] \geq 0. \quad (27)$$

As a result, minimizing the error of the joint state (21) can be achieved by maximizing the probability of detection (24), and the robot control law can be obtained by solving the following constrained optimization problem in  $\mathbf{u}_r(k)$ :

$$\begin{aligned} \max_{\mathbf{u}_r(k)} \quad & P_d[\mathbf{q}_r(k+1)] \\ \text{s.t.} \quad & \mathbf{q}_r(k+1) = \mathbf{q}_r(k) + \mathbf{B}_r(k)\mathbf{u}_r(k)\delta t \end{aligned} \quad (28)$$

### B. Robot Control Law

A robot control law that takes into account the tracking and localization performance presented in Section IV-A and the models in Section II, while being characterized by low computational complexity so as to afford realtime implementation can be obtained as follows.

At any discrete time step  $k$ , the robot control inputs are computed so as to maximize the probability of detection at the next time step,  $(k+1)$ , subject to the robot kinematics. The solution of the constrained optimization problem (28) can be obtained by moving in the direction of the adjoined gradient which, in this case, can be obtained analytically, thus providing the control law in closed form. As a first step, the Jacobian for (28) can be written as,

$$\frac{\partial P_d[\mathbf{q}_r(k+1)]}{\partial \mathbf{u}_r(k)} = \frac{\partial P_d[\mathbf{q}_r(k+1)]}{\partial \mathbf{q}_r(k+1)} \frac{\partial \mathbf{q}_r(k+1)}{\partial \mathbf{u}_r(k)}. \quad (29)$$

where

$$\frac{\partial P_d[\mathbf{q}_r(k+1)]}{\partial \mathbf{q}_r(k+1)} = \begin{bmatrix} \frac{\partial}{\partial x_r} \{P_d[\mathbf{q}_r(k+1)]\} \\ \frac{\partial}{\partial y_r} \{P_d[\mathbf{q}_r(k+1)]\} \\ \frac{\partial}{\partial \theta_r} \{P_d[\mathbf{q}_r(k+1)]\} \end{bmatrix}. \quad (30)$$

Each term of the above expression (30) is computed by derivatives of integrals. For example, if the robot's FoV is approximated by a triangle  $ABC$  as in Fig. 2, the first entry

of (30) can be calculated as follows:

$$\begin{aligned} \frac{\partial}{\partial x_r} P_d[\mathbf{q}_r(k+1)] &= \frac{\partial}{\partial x_r} \int_{\mathcal{S}[\mathbf{q}_r(k+1)]} f_t(\mathbf{x}_t) d\mathbf{x}_t \\ &= \int_{\mathcal{S}[\mathbf{q}_r(k+1)]} \frac{\partial}{\partial x_r} f_t(\mathbf{x}_t) d\mathbf{x}_t + \oint_{\partial \mathcal{S}[\mathbf{q}_r(k+1)]} (\mathbf{v}_x \cdot \mathbf{n}) f_t(\mathbf{x}_t) d\mathbf{x}_t \end{aligned} \quad (31)$$

where  $\mathbf{v}_x = [1 \ 0]^T$  is the velocity of the robot FoV,  $\mathbf{n}$  is the outward-pointing unit normal vector along the boundary of the robot FoV. The outward-pointing unit normal vectors can be obtained through the heading of the robot and the opening angle of the robot FoV, as shown in Fig. 2 (a), i.e.,

$$\begin{aligned} \mathbf{n}_1 &= \mathbf{C}(\pi/2 + \alpha/2) [\cos \theta_r \ \sin \theta_r]^T \\ \mathbf{n}_2 &= [\cos \theta_r \ \sin \theta_r]^T \\ \mathbf{n}_3 &= \mathbf{C}(-\pi/2 - \alpha/2) [\cos \theta_r \ \sin \theta_r]^T \end{aligned} \quad (32)$$

where  $\mathbf{C}(\cdot)$  is the  $2 \times 2$  rotation matrix. Moreover, since  $f_t(\mathbf{x}_t)$  is not a function of  $\mathbf{q}_r$ ,  $\frac{\partial}{\partial \mathbf{q}_r} f_t(\mathbf{x}_t) = 0$ . In addition, (25) gives the analytical form of  $f_t$ . Then the parietal derivative in (31) can be simplified as follows,

$$\begin{aligned} \frac{\partial}{\partial x_r} P_d[\mathbf{q}_r(k+1)] &= \int_{AB} (\mathbf{v}_x \cdot \mathbf{n}_1) \exp[-\frac{1}{2}(\mathbf{x}_t - \boldsymbol{\mu}_t)^T \boldsymbol{\Sigma}_t^{-1}(\mathbf{x}_t - \boldsymbol{\mu}_t)] d\mathbf{x}_t \\ &+ \int_{BC} (\mathbf{v}_x \cdot \mathbf{n}_2) \exp[-\frac{1}{2}(\mathbf{x}_t - \boldsymbol{\mu}_t)^T \boldsymbol{\Sigma}_t^{-1}(\mathbf{x}_t - \boldsymbol{\mu}_t)] d\mathbf{x}_t \\ &+ \int_{CA} (\mathbf{v}_x \cdot \mathbf{n}_3) \exp[-\frac{1}{2}(\mathbf{x}_t - \boldsymbol{\mu}_t)^T \boldsymbol{\Sigma}_t^{-1}(\mathbf{x}_t - \boldsymbol{\mu}_t)] d\mathbf{x}_t \end{aligned} \quad (33)$$

Similarly, the second entry of (30) can be obtained in the same way, except that  $\mathbf{v}_y = [0 \ 1]^T$ , as follows,

$$\begin{aligned} \frac{\partial}{\partial y_r} P_d[\mathbf{q}_r(k+1)] &= \int_{AB} (\mathbf{v}_y \cdot \mathbf{n}_1) \exp[-\frac{1}{2}(\mathbf{x}_t - \boldsymbol{\mu}_t)^T \boldsymbol{\Sigma}_t^{-1}(\mathbf{x}_t - \boldsymbol{\mu}_t)] d\mathbf{x}_t \\ &+ \int_{BC} (\mathbf{v}_y \cdot \mathbf{n}_2) \exp[-\frac{1}{2}(\mathbf{x}_t - \boldsymbol{\mu}_t)^T \boldsymbol{\Sigma}_t^{-1}(\mathbf{x}_t - \boldsymbol{\mu}_t)] d\mathbf{x}_t \\ &+ \int_{CA} (\mathbf{v}_y \cdot \mathbf{n}_3) \exp[-\frac{1}{2}(\mathbf{x}_t - \boldsymbol{\mu}_t)^T \boldsymbol{\Sigma}_t^{-1}(\mathbf{x}_t - \boldsymbol{\mu}_t)] d\mathbf{x}_t \end{aligned} \quad (34)$$

Let  $\text{sign}(\cdot)$  denote the sign function, and  $\ell$  denote the distance from a point on the boundary of the FoV to the point  $A$ . Then, the third entry of (30) can also be calculated analytically as follows,

$$\begin{aligned} \frac{\partial}{\partial \theta_r} P_d[\mathbf{q}_r(k+1)] &= \int_{AB} -\text{sign}(d\theta_r) \ell \exp[-\frac{1}{2}(\mathbf{x}_t - \boldsymbol{\mu}_t)^T \boldsymbol{\Sigma}_t^{-1}(\mathbf{x}_t - \boldsymbol{\mu}_t)] d\mathbf{x}_t \\ &+ \int_{CA} \text{sign}(d\theta_r) \ell \exp[-\frac{1}{2}(\mathbf{x}_t - \boldsymbol{\mu}_t)^T \boldsymbol{\Sigma}_t^{-1}(\mathbf{x}_t - \boldsymbol{\mu}_t)] d\mathbf{x}_t \end{aligned} \quad (35)$$

Alg.1 Implementation of the optimized-visibility method

Now let us consider the the second term of (29), which essentially is the robot motion model, i.e.,

$$\frac{\partial \mathbf{q}_r(k+1)}{\partial \mathbf{u}_r(k)} = \mathbf{B}_r(k) \delta t \quad (36)$$

Thus, we have computed the Jacobian (33)-(36). The optimized-visibility method is summarized in Alg. 1, where  $\eta$  is the learning rate and  $\epsilon$  is a predefined threshold [30]. Notice that Alg. 1 does handle the situation when the target is out of the FoV for multiple steps since this paper focuses on analyzing the ability of avoiding target loss.

## V. SIMULATION RESULTS

In order to validate the effectiveness of the proposed approach, we conduct various simulations under different conditions, and compare the performance to that of a state-of-the-art potential field approach, which controls the robot as a trailer [23]. Specifically, it first calculates a force,  $\mathbf{f}_p(k)$ , proportional to the distance between the center of the inscribed circle of the FoV,  $\mathbf{x}_p(k)$ , and the estimated mean of target position distribution,  $\boldsymbol{\mu}_t(k)$ .

$$\mathbf{f}_p(k) = c_p \|\mathbf{x}_p(k) - \boldsymbol{\mu}_t(k)\|, \quad (37)$$

where  $c_p$  is a constant. Then, the potential approach projects the force along the robot heading and perpendicular to the robot heading. Let  $\theta_p(k)$  denote the angle between the robot heading and the direction from  $\mathbf{x}_p(k)$  to  $\boldsymbol{\mu}_t(k)$ . The control is determined as a linear function of the projections, such that

$$v_r(k) = a_p \|\mathbf{f}_p(k)\| \cos \theta_p(k) \quad (38)$$

$$\omega_r(k) = b_p \|\mathbf{f}_p(k)\| \sin \theta_p(k) \quad (39)$$

where  $a_p$  and  $b_p$  are constants.

For the results presented in Fig. 3 and Fig. 4, the robot and the target are assumed to move in a workspace of  $\mathcal{W} = [-50, 50] \times [-50, 50] \text{ m}^2$ . The sensor's FoV is assumed to have a radius,  $\gamma = 2.5 \text{ m}$ , and an opening angle,  $\alpha = \pi/6 \text{ rad}$ . This choice of parameters results in a relative small sensor's FoV as compared to the workspace, so that target is easy to disappear from the FoV. The sampling

time,  $\delta t$ , is assumed to be 0.2 sec, which means the robot makes both the proprioceptive measurements,  $\mathbf{z}_r(k)$ , and the exteroceptive measurements,  $\mathbf{z}_t(k)$ , every 0.2 second. For the proprioceptive measurements, the noise is 2% of the maximum speed the robot can travel at and  $\pi/180 \text{ rad/sec}$  for the angular speed measurement. In all the tests, it is assumed that the maximum speed that the robot is able to achieve is 3 m/sec, and the maximum angular speed for the robot is 0.5 rad/sec. As a result, the proprioceptive noise covariance is  $\mathbf{R}_r \approx \text{diag}([36 \ 3]) \times 10^{-4}$ . Note that we did not restrict the robot to travel forward, which means the robot can travel backward and reach the speed limit of 3 m/sec. For the exteroceptive measurements, the noise level is 3% of the maximum detection radius of the FoV for the range measurement, and  $\pi/36 \text{ rad}$  for the bearing measurement, and the noise covariance is  $\mathbf{R}_t \approx \text{diag}([81 \ 76]) \times 10^{-4}$ .

In this test, the target adopts a constant velocity model:

$$\Phi_t = \begin{bmatrix} 1 & 0 & \delta t & 0 \\ 0 & 1 & 0 & \delta t \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}. \quad (40)$$

The noise in the target state propagation equation (7) makes the target move randomly in the workspace. It is assumed that  $\mathbf{G} = \mathbf{I}$  and the noise of the target position is correlated with its speed. The noise matrix is assumed to be

$$\mathbf{Q} = \begin{bmatrix} \delta t^3 \sigma^2 / 3 & 0 & \delta t^2 \sigma^2 / 2 & 0 \\ 0 & \delta t^3 \sigma^2 / 3 & 0 & \delta t^2 \sigma^2 / 2 \\ \delta t^2 \sigma^2 / 2 & 0 & \delta t \sigma^2 & 0 \\ 0 & \delta t^2 \sigma^2 / 2 & 0 & \delta t \sigma^2 \end{bmatrix}, \quad (41)$$

where  $\sigma$  is chosen to be 0.5 m/sec, which is large enough to prevent the target from moving in a straight line. The initial state of the target is assumed to be  $\mathbf{q}_t(0) = [0 \ 0 \ 0 \ 0]$ , which enables the target to move in every direction with the same probability.

Figure 3(a) shows the tracking performance of the proposed gradient descent approach in one particular realization, for  $\eta = 1$  and  $\epsilon = 10^{-3}$ , from which it is clear that the robot is able to track the target throughout the simulation. With the identical setup, the tracking result of the potential method is shown in Fig. 3(b). As evident, the robot lost the target at time step  $k = 170$ , while the proposed optimized visibility approach reliably tracks the target (see Fig. 3(a)). Figure 4 shows comparison between the estimated and true target trajectories. The deviation of estimated target trajectory from the true target trajectory decreases.

To further justify the result in Fig. 3, we have performed various simulations with different parameters. In particular, we studied the impact of FoV opening angle  $\alpha$  and the radius  $\gamma$  on the efficiency of the potential and the proposed optimized visibility methods. In order to evaluate the tracking performance, the percentage of target detection,  $\beta$ , is defined as the number of successful target detections divided by the total number of simulation steps. The parameter  $\eta$  is set to one for all the simulations and  $\epsilon$  is  $10^{-3}$ . The results are summarized in Fig. 5 and Fig. 6, which show that

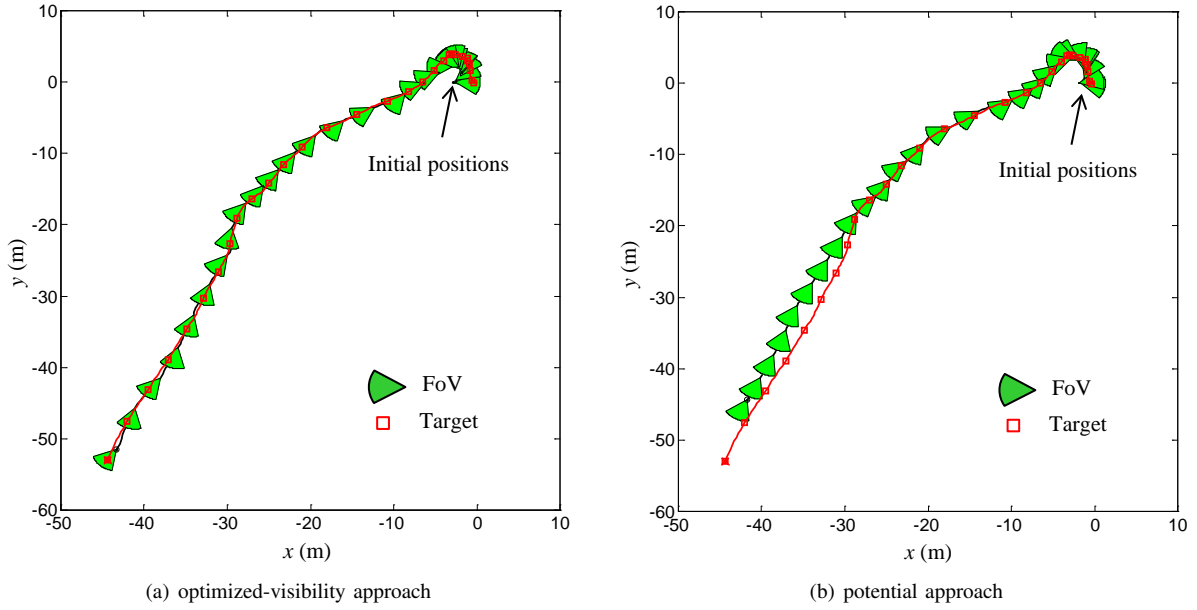

Fig. 3. An example of the simulation result where the visibility optimized approach tracks enables the robot to keep the target in its FoV all the time while the potential field method loses the target around 200 time step, for a FoV with  $\alpha = \pi/6$  rad and  $\gamma = 2.5$  m.

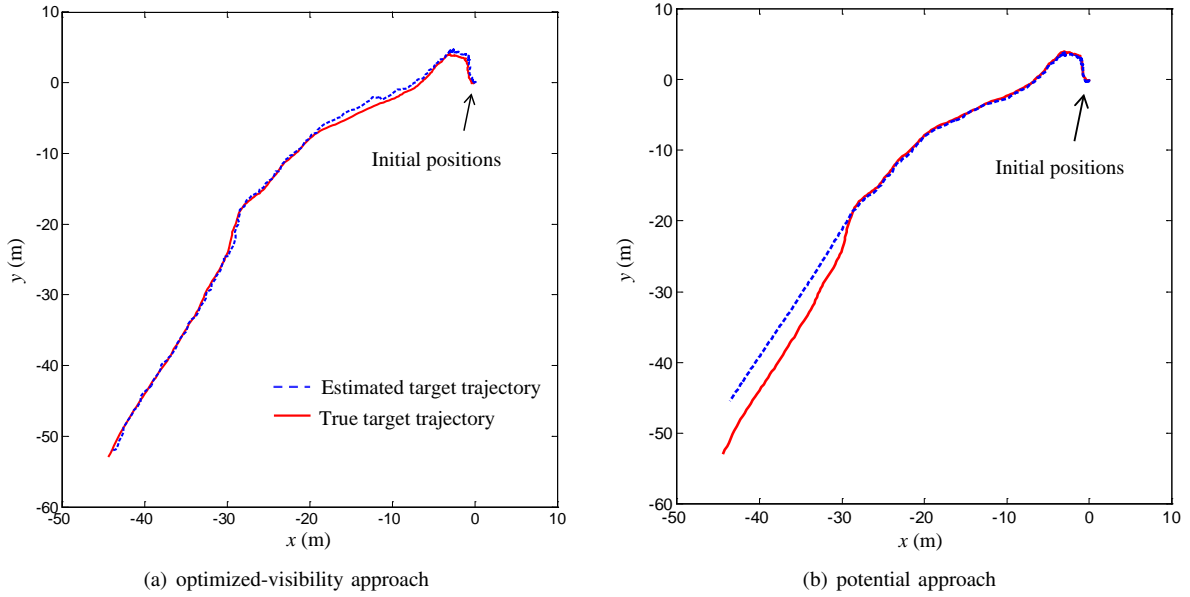

Fig. 4. The estimated and true target trajectories obtained by the optimized visibility approach and the potential field approach for the example in Fig. 3.

the optimized visibility approach outperforms the potential method with higher detection percentage.

## VI. CONCLUSIONS AND FUTURE WORK

In this paper, we have studied the problem of target tracking using mobile robots (sensors), by focusing on optimal motion planning for the tracking robots in order to achieve best tracking performance. In particular, within the EKF framework of jointly estimating the robot pose and target state, the robot motion planning problem has been formulated as maximizing the target-detection probability. Furthermore, an optimized visibility approach for solving this optimization problem has been introduced, which is derived analytically

based on the optimality condition. Numerical simulation results have demonstrated that the proposed approach outperforms the state-of-the-art potential approach.

In future work, the current one-step-ahead optimization will be extended to the multiple-step-ahead cases, and the proposed optimized visibility method will be generalized to the problem of simultaneous localization, mapping, and target tracking, which is particularly important for mobile robots working in dynamic environments. Moreover, different estimation algorithms will be investigated for a given application where the EKF may not be sufficient (e.g., it is degraded due to larger linearization errors). In particular, it

is noted that the recently developed iSAM algorithms could be an interesting alternative [27], [28], [31], which will be considered for this problem.
